1- Each directory contains the outputs of requests sent to the corresponding service, also contains screenshots for the docker image build and container creation and log file (based on the requirements, log files are for catalog and order only)

2- All requests shown in all directories can be sent to the front-end service and then it forwards them to the catalog or order, or they can be sent directly to the corresponding server (you can see the two ways in the directories)

3- When making a purchase request:
   a- Order server log: will log just one request. (actual purchase request)
   b- Catalog server log: will log two requests coming from the order service, the first one is for checking the item availability, and the second one is for updating(decreasing) the item stock if it is available.

4- The "whole-system-output" directory contains the output of the main three requests mentioned in the appendix of the project description, and the other directories contain more screens and requests.
